Abstract

Cardiac ultrasound artifacts are common findings and inevitable as they originate from the physical properties of the US. This document provides a uniform and structured approach to the US imaging artifacts, starting from the mechanism behind the artifact generation, the appearance of the artifact on the image, the clinical impact of the artifact on the diagnosis and management of the patient, examples of real cases and more importantly how we can diminish or mitigate the artifact.

Everyone who is involved in performing or interpreting cardiac ultrasound should be familiar with the artifacts and misdiagnosis of artifacts which in some instances may lead to serious clinical consequences. Despite continued improvement in ultrasound imaging technologies, artifacts are still common in all echocardiographic modes, including 2D, spectral and color Doppler as well as 3D echocardiography.

Cardiotoxicity is the loss of the heart muscle's ability to contract effectively, often due to chemotherapy or radiation therapy. This study uses interpretable machine learning to predict post-chemotherapy cardiotoxicity using radiomics features extracted from the baseline echocardiography images. The study involved 100 cancer patients at Rajaie Cardiovascular Medical and Research Center. Baseline echocardiography images were used to extract radiomics features such as the left ventricular ejection fraction. According to the 12-month follow-up echocardiography, cardiotoxicity is defined as EF decline. Machine learning models predicted chemotherapy-induced cardiotoxicity based on radiomics features, with their significance confirmed via SHapley Additive exPlanations (SHAP) and Permutation-based Feature Importance Test (PermFIT). Among the 100 patients with a mean age of 54.5 ± 13.7 , 41 patients (41%) experienced cardiotoxicity. For the short-axis view, the K-nearest neighbors (KNN) and Linear Support Vector Machine (SVM) models achieved accuracies of 0.92 and 0.90, respectively, with the best outcome of 92%. For the 4-chamber view, SVM and KNN reached accuracies of 0.88 and 0.83. These findings underscore the potential of machine learning, especially using short-axis echocardiography, to enhance early diagnosis of cardiotoxicity in chemotherapy patients.
